Find a jig on ozwala.com and install it

A member browses ozwala.com's public jig directory, opens a jig, follows its repository link, and installs the jig into their desktop app from that link. The CLI then lists it, installed from the very address the directory gave.

That last check is the point: the directory and the install path are the same object. What the app installs is what the listing leads to, and the jig remembers where it came from, so an update later fetches from there.

What you can count on

- A jig in the public directory leads, through its listing, to the repository it lives in
- The desktop app installs the jig from the link the listing gave
- The CLI lists the installed jig, and it records the listing's link as its source

Where it works

On ozwala.com, in the desktop app, and on the command line. Each of these is checked, on every surface named, by the ozwala-usecases harness.
