

Push a jig to a new GitLab repository, with a token saved once for the host

Someone on a self-hosted GitLab saves one token for the host, in the CLI or in Settings > Git, and from then on every jig there pushes and installs without asking for one: a new repository is created in a group, and a second jig on the same host needs no token of its own. The token is never shown again, only the host it is for.

Push a jig to a new GitLab repository, with a token saved once for the host

Someone on a self-hosted GitLab saves one token for the host, in the CLI or in Settings > Git, and from then on every jig there pushes and installs without asking for one: a new repository is created in a group, and a second jig on the same host needs no token of its own. The token is never shown again, only the host it is for.

What you can count on

- A token is saved for the GitLab host, apart from any jig
- A jig is pushed to a new private repository created in a group, with no token asked for
- The host is listed among saved tokens, and the token itself never appears
- A second jig on the same host pushes with the host's token
- Another machine with the host's token installs it without being asked for one

Where it works

In the desktop app and on the command line. Each of these is checked, on every surface named, by the ozwala-usecases harness.
