

Push a jig to a repository you already have, over SSH

A developer keeps their jig in a repository on a git service Ozwala knows nothing about, reached over SSH with their usual key. They give Ozwala the repository's address and push; another machine installs it the same way. Until the server's host key is in known_hosts, Ozwala refuses to connect and says which fingerprint it was offered and how to trust it.

Push a jig to a repository you already have, over SSH

A developer keeps their jig in a repository on a git service Ozwala knows nothing about, reached over SSH with their usual key. They give Ozwala the repository's address and push; another machine installs it the same way. Until the server's host key is in known_hosts, Ozwala refuses to connect and says which fingerprint it was offered and how to trust it.

What you can count on

- An unknown SSH host is refused, naming its key's fingerprint and the ssh-keyscan line
- Once the host is trusted, the jig is pushed to the existing repository over SSH
- Another machine installs it over SSH

Where it works

In the desktop app and on the command line. Each of these is checked, on every surface named, by the ozwala-usecases harness.
