Two machines change the same jig, and nobody's work is lost silently

Someone changes their jig on the laptop and on the workstation. The first push wins; the second machine is told to update first, and its update refuses to throw away its own changes until the person says to.

What you can count on

- The first machine to push succeeds
- The second machine’s push is refused, telling it to update first
- The second machine’s update will not discard its changes unless the person says so
- Told to discard, the second machine takes the first machine’s version

Where it works

In the desktop app and on the command line. Each of these is checked, on every surface named, by the ozwala-usecases harness.
